# Minimum effort of reorganisation distance 

Lect. Dorin MITRUT<br>Economic Cybernetics Department, Academy of Economic Studies Bucharest

#### Abstract

The directional efficiency measures reveal how inefficient (or efficient) is a decision-making unit on the direction selected but it nothing says about the purport of this direction and who is the direction who must be selected. Also, the directional models fix from the beginning same direction for every production unit albeit they are different situated respecting frontier. It is very probable that each production unit prefer certain directions, these directions depending by her present structure, present dimension, future objectives etc. We propose in this section to introduce the "effort" function that a possible answer of this aspect of analysis.

Key words: Efficiency measures, Directional efficiency measures, Efficient frontier, Data envelopment analysis.

1Effort function
The reasoning following are based at hypothesis that the decision-making units propose to become efficient.
Because efficiency measurement is done relative to efficient frontier and the projection point of decision-making unit on this direction is the efficient decisionmaking unit appropriate (so desirable) it is natural to see how difficult is this action and how is the most facile alternative.
In this purpose we introduce the "effort" function defined by:
$\mathrm{f}_{\text {eff }}: R_{+}^{m+n} \times R_{+}^{m+n} \rightarrow R_{+}$
where $\mathrm{f}_{\mathrm{eff}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}, \mathrm{y}\right)=$ "the minimum necessary effort to pass at ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ) structure in ( $\mathrm{x}, \mathrm{y}$ ) structure"

If $\|x, y\|$ is norm of ( $x, y$ ) vector then the value:

$$
\begin{aligned}
& \mathrm{f}_{\mathrm{eff}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}_{0}+\theta \frac{g_{x}}{\left\|g_{x}, g_{y}\right\|}, \mathrm{y}_{0}+\theta \frac{g_{y}}{\left\|g_{x}, g_{y}\right\|}\right) \\
& =\mathrm{f}_{\mathrm{eff}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)+\theta \frac{\left(g_{x}, g_{y}\right)}{\left\|g_{x}, g_{y}\right\|}\right)
\end{aligned}
$$

represent the minimum necessary effort for the reorganisation with $\theta$ units par ( $\mathrm{g}, \mathrm{g}_{\mathrm{y}}$ ) direction starting of ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ).
We suppose to effort function have the property:
a) $f_{\text {eff }}$ is continue
b) $\mathrm{f}_{\mathrm{eff}} \geq 0(\forall)\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}, \mathrm{y}\right) \in R_{+}^{m+n} \times R_{+}^{m+n}$
c) $\mathrm{f}_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}, \mathrm{y}\right)=0 \Leftrightarrow\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)=(\mathrm{x}, \mathrm{y})$

We define the distance function $\mathrm{D}_{\mathrm{R}}(\mathrm{x}, \mathrm{y})$ by:

where $\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}: \mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right)=$ the directional technology distance function for ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ) on ( $\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}$ ) direction.
Practically, this distance represent, for a feasible production ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ), smallest effort necessary for become efficient and, for an 1. If we note:
infeasible production ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ), smallest effort with which one can reach this performance on the basis of technology gives.
For practical compute of this distance we make following observations.

$$
f_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right)\right)=f_{\text {eff }\left(x_{0}, y_{0}\right)}\left(\mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right)
$$

$$
\text { then } f_{\text {eff }\left(x_{0}, y_{0}\right)}\left(\mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right)=f_{\text {eff }\left(x_{0}, y_{0}\right)}\left(\lambda \mathrm{g}_{\mathrm{x}}, \lambda \mathrm{~g}_{\mathrm{y}}\right), \lambda>0
$$

Indeed, because $\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}, \mathrm{y} ; \lambda \mathrm{g}_{\mathrm{x}}, \lambda \mathrm{g}_{\mathrm{y}}\right)=\frac{1}{\lambda} \mathrm{D}_{\mathrm{T}}\left(\mathrm{x}, \mathrm{y} ; \mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right)$, result:

$$
\begin{aligned}
& f_{e f f\left(x_{0}, y_{0}\right)}\left(\lambda \mathrm{g}_{\mathrm{x}}, \lambda \mathrm{~g}_{\mathrm{y}}\right)=f_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \lambda \mathrm{g}_{\mathrm{x}}, \lambda \mathrm{~g}_{\mathrm{y}}\right) \cdot\left(-\lambda g_{y}, \lambda g_{y}\right)\right)= \\
& f_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\frac{1}{\lambda} \mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right) \cdot\left(-\lambda g_{y}, \lambda g_{y}\right)\right)= \\
& f_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right)\right)
\end{aligned}
$$

So, for compute the distance function $\mathrm{D}_{\mathrm{R}}(\mathrm{x}, \mathrm{y})$ is sufficient to compute only on normat direction.

$$
\min _{\substack{g_{y} \in R^{m} \\ g_{y} \in R_{+}^{n}}} f_{e f f}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right)\right)
$$

have solution. Can be much direction for which expects the minimum of the problem, therefore much projection of ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ) on efficient frontier but everyone necessitating same effort for be reach.

$$
(\alpha, \beta)=\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; g_{x}^{\min }, g_{y}^{\min }\right) \cdot\left(-g_{x}^{\min }, g_{y}^{\min }\right)
$$

3. If T technology is free disposable then with $\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right) \geq 0$ and $\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right) \neq 0 \Rightarrow(-\alpha, \beta) \geq$ the projection point(s) of ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ) is more efficient than $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ if $\mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)>0$ and less efficient if $\mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)<0$.
Indeed, if $\mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)>0$ then exist $(\mathrm{x}, \mathrm{y}) \in$ $\mathrm{T},(\mathrm{x}, \mathrm{y}) \neq\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ and $\mathrm{x} \leq \mathrm{x}_{0}, \mathrm{y} \geq \mathrm{y}_{0}$. Pursuant to free disposable hypothesis $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) \in \mathrm{T}$. Because $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) \in \mathrm{T} \Leftrightarrow$ $\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}, \mathrm{y} ; \mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right) \geq 0$ for each direction ( $\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}$ )

$$
\begin{gathered}
\Rightarrow\left\{\begin{array} { c } 
{ \mathrm { D } _ { \mathrm { T } } ( \mathrm { x } _ { 0 } , \mathrm { y } _ { 0 } ; g _ { x } ^ { \text { min } } , g _ { y } ^ { \text { min } } ) \cdot ( - g _ { x } ^ { \text { min } } ) \geq 0 } \\
{ \mathrm { D } _ { \mathrm { T } } ( \mathrm { x } _ { 0 } , \mathrm { y } _ { 0 } ; g _ { x } ^ { \text { min } } , g _ { y } ^ { \text { min } } ) \cdot g _ { y } ^ { \text { min } } \leq 0 }
\end{array} \Rightarrow \left\{\begin{array}{l}
\alpha \geq \mathrm{x}_{0} \\
\beta \leq \mathrm{y}_{0}
\end{array} \Rightarrow\right.\right. \\
\Rightarrow(-\alpha, \beta) \leq\left(-\mathrm{x}_{0}, \mathrm{y}_{0}\right) \text { that is to say }(\alpha, \beta) \text { is less efficient than }\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) .
\end{gathered}
$$

4. $\mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)=0 \Leftrightarrow(\exists) \mathrm{g}=\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right), \mathrm{g} \neq 0$ and $\mathrm{g} \geq 0$ that $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) \in \operatorname{Isoq}_{\mathrm{g}}(\mathrm{T})$

$$
" \Rightarrow "
$$

$\mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)=0 \Rightarrow(\exists)\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right)$ that $f_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right)\right)=0$
$\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) \in \operatorname{Isoq}_{\mathrm{g}}(\mathrm{T}) \Rightarrow \mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right)=0 \Rightarrow\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) \in \mathrm{T} \Rightarrow$
$\Rightarrow f_{e f f}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right)\right)=f_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}_{0} \mathrm{y}_{0}\right)=0 \Rightarrow$

For a direction $\left(\mathrm{g}_{\mathrm{x}}^{\mathrm{min}}, \mathrm{g}_{\mathrm{y}}^{\mathrm{min}}\right)$ which gives the minimum, the projection point(s) of ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ) on efficient frontier is:

$$
\begin{aligned}
& \Rightarrow\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)=\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right) \Rightarrow \\
& \Rightarrow \mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right)=0 \Rightarrow \\
& \Rightarrow \mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right)=0 \Rightarrow\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) \in \operatorname{Isoq}_{\mathrm{g}}(\mathrm{~T})
\end{aligned}
$$

$$
\Rightarrow f_{e f f}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right)\right)=f_{e f f}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}_{0} \mathrm{y}_{0}\right)=0 \Rightarrow
$$

$\Rightarrow \min _{\substack{g_{y} \in R_{+n}^{n} \\ g_{y} \in R_{+}^{n}}} f_{e f f}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right)\right)=0 \Rightarrow$

$$
\left.\begin{array}{l}
g_{\in} \in R^{m} \\
g_{y} \in R_{+}^{n}
\end{array}\right)
$$

$\Rightarrow \mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)=0$
$\left(-\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ that is to say $(\alpha, \beta)$ is more efficient than $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$.
if $\mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)<0 \Rightarrow(\nexists)(\mathrm{x}, \mathrm{y}) \in \mathrm{T}$ with $(-\mathrm{x}, \mathrm{y})$ $\geq\left(-\mathrm{x}_{0}, \mathrm{y}_{0}\right) \Rightarrow$
$\Rightarrow \mathrm{D}_{\mathrm{T}}\left(\mathrm{x}, \mathrm{y} ; \mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right)<0$ for each direction $\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right)$ with $\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right) \geq 0$ and $\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right) \neq 0 \Rightarrow$

$$
\Rightarrow \mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)=0
$$

## 2. Algorithm for compute the efficiency measurement

For a technology given by $k$ observed DMU the practical compute of distance function $D_{R}(x, y)$ can be realised thus:
step 1. We find, using one among the measures who eliminate the slacks, i.e. Färe-Lovell, Zieschang etc, the DMUs that are efficient in input and in output.
step 2 . We find, using one soft, e.g. CDD, the convex hull of DMUs set, i.e. general convex polyhedron in $R^{m+n}$ given by a system of linear inequalities:
$P=\{x / A \cdot(x, y) \leq b\}$
where $A$ is a $p x(m+n)$ real matrix and $b$ is a real $p$ dimensional vector.
step 3. For every linear inequalities we find the DMUs situated on the $(m+n)$ dimensional plan:
$P_{\mathrm{i}}: \sum_{j=1}^{m} a_{i j} x_{j}+\sum_{j=1}^{n} a_{i, m+j} y_{j}=b_{i} \quad \mathrm{i}=1, \mathrm{p}$
step 4. We compute for given $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ production the directional distance $\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right)$ for a certain direction $\left(g_{x}, g_{y}\right) \geq 0$ direction. If $D_{T}\left(x_{0}, y_{0} ; g_{x}, g_{y}\right)$ $\geq 0$ then $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ is feasible and if $\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right)<0$ then $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ is infeasible.
step 5. If $\mathrm{F}=\left\{\mathrm{DMU} / \mathrm{DMU} \in P_{\mathrm{i}}\right\}$, $\mathrm{X}^{\mathrm{i}}$ is the $\operatorname{card}\left(\mathrm{F}^{\mathrm{i}}\right) \times \mathrm{m}$ matrix of inputs of the $\mathrm{F}^{i}$ DMUs and $\mathrm{Y}^{i}$ is the $\operatorname{card}\left(\mathrm{F}^{\mathrm{i}}\right) \times \mathrm{n}$ matrix of outputs of the $\mathrm{F}^{\mathrm{i}}$ DMUs then the program:

$$
\begin{gathered}
f_{e f f}^{i}=\min _{\lambda} f_{e f f}\left(x_{0}, y_{0} ;(X Y)_{i}^{T} \lambda\right) \\
\left\{\begin{array}{l}
\sum_{j=1}^{\operatorname{card}\left(F_{i}\right)} \lambda_{j}=1 \\
X_{i}^{T} \lambda \leq x_{0} \\
Y_{i}^{T} \lambda \geq y_{0} \\
\lambda \geq 0
\end{array}\right.
\end{gathered}
$$

give the minimum effort necessary for reach the $P_{\mathrm{i}}$ face on a $\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right) \geq 0$ direction for a feasible DMU and the program:

$$
\begin{gathered}
f_{e f f}^{i}=\min _{\lambda} f_{\text {eff }}\left((X Y)_{i}^{T} \lambda ; x_{0}, y_{0}\right) \\
\left\{\begin{array}{l}
\sum_{j=1}^{\operatorname{card}\left(F_{i}\right)} \lambda_{j}=1 \\
X_{i}^{T} \lambda \geq x_{0} \\
Y_{i}^{T} \lambda \leq y_{0} \\
\lambda \geq 0
\end{array}\right.
\end{gathered}
$$

give the minimum effort necessary for obtain ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ) technology starting from $P_{\mathrm{i}}$ face on a $\left(g_{x}, g_{y}\right) \geq 0$ direction, if $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ is infeasible.
step 6. $\mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)=f_{\text {eff }}^{i_{0}}= \begin{cases}\min _{i=1, p} f_{\text {eff }}^{i} & \text { if }\left(\mathrm{x}_{0} \mathrm{y}_{0}\right) \text { is feasible } \\ -\min _{i=1, p} f_{e f f}^{i} & \text { if }\left(\mathrm{x}_{0} \mathrm{y}_{0}\right) \text { is infeasible }\end{cases}$
step 7. Projection point of $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ on T frontier is $\left(\mathrm{x}_{0}^{\mathrm{pp}}, \mathrm{y}_{0}^{\mathrm{pp}}\right)=(\mathrm{XY})_{\mathrm{i}_{0}}^{\mathrm{T}} ?_{\mathrm{i}_{0}}^{0}$ where $?_{\mathrm{i}_{0}}^{0}$ is the solution of ib program.
step 8. Direction of projection is $\left(\mathrm{g}_{\mathrm{x}}^{0}, \mathrm{~g}_{\mathrm{y}}^{0}\right)= \begin{cases}\left(\mathrm{x}_{0}-\mathrm{x}_{0}^{\mathrm{pp}}, \mathrm{y}_{0}^{\mathrm{pp}}-\mathrm{y}_{0}\right) & \text { if }\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) \text { is feasible } \\ \left(\mathrm{x}_{0}^{\mathrm{pp}}-\mathrm{x}_{0}, \mathrm{y}_{0}-\mathrm{y}_{0}^{\mathrm{pp}}\right) & \text { if }\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) \text { is infeasible }\end{cases}$

## 3. Final considerations over the results

The preceding algorithm finds the direction towards the efficient technology easiest has derived but it nothing say who is the route for this.
For an observed ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ) DMU a possible information is done by:
$\mathrm{f}_{\mathrm{eff}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}_{0}+\theta \frac{g_{x}}{\left\|g_{x}, g_{y}\right\|}, \mathrm{y}_{0}+\theta \frac{g_{y}}{\left\|g_{x}, g_{y}\right\|}\right)$
who represent the minimum necessary effort for the reorganisation with $\theta$ units $\operatorname{par}\left(\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}\right)$ direction starting of $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$.
Then $\min _{\left(\mathrm{g}_{\mathrm{x}} \mathrm{g}_{\mathrm{y}}\right) \geq 0} \mathrm{f}_{\mathrm{eff}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}_{0}+\theta \frac{g_{x}}{\left\|g_{x}, g_{y}\right\|}, \mathrm{y}_{0}+\right.$ $+\theta \frac{g_{y}}{\left\|g_{x}, g_{y}\right\|}$ ) represent minimum effort for a reorganisation with $\theta$ units starting of
$\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ and $\left(\mathrm{g}_{\mathrm{x}}^{?}, \mathrm{~g}_{\mathrm{y}}^{?}\right)$ the corresponding The value: direction.

$$
f_{e f f}^{\theta}=f_{e f f}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}^{\theta}, \mathrm{g}_{\mathrm{y}}^{\theta}\right) \cdot\left(-\mathrm{g}_{\mathrm{x}}^{\theta}, \mathrm{g}_{\mathrm{y}}^{\theta}\right)\right)
$$

represent necessary effort for to realise the efficient technology corresponding of $\left(\mathrm{g}_{\mathrm{x}}^{?}, \mathrm{~g}_{\mathrm{y}}^{?}\right)$ direction. It is evident that $\mathrm{D}_{\mathrm{R}}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right) \leq f_{\text {eff }}^{\theta}$.
The value: $E f f_{A L}^{\theta}=\frac{f_{e f f}^{\theta}}{D_{R}\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)}$

$$
f_{e f f}\left(x_{0}, y_{0}\right)\left(\mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right)=f_{e f f}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ;\left(\mathrm{x}_{0} \mathrm{y}_{0}\right)+\mathrm{D}_{\mathrm{T}}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{g}_{\mathrm{x}}, \mathrm{~g}_{\mathrm{y}}\right) \cdot\left(-g_{y}, g_{y}\right)\right)
$$

represent the necessary effort to realise the efficient technology corresponding of ( $\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}$ ) direction.
If $\left\{\mathrm{DMU}_{\mathrm{i}} / \mathrm{i}=1, \mathrm{k}\right\}$ is the observed DMU
set then: $f_{\text {eff }}^{T}\left(\mathrm{~g}_{\mathrm{x}} \mathrm{g}_{\mathrm{y}}\right)=\sum_{\mathrm{i}=1}^{\mathrm{k}} f_{\text {eff }\left(\mathrm{x}_{\mathrm{i}} \mathrm{y}_{\mathrm{i}}\right)}\left(g_{x} g_{y}\right)$ is the necessary effort that every DMU realise the efficient technology corresponding of ( $\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}$ ) direction.
The value: $f_{\text {effopt }}^{T}=\min _{g_{x} g_{y}} f_{\text {eff }}^{T}\left(\mathrm{~g}_{\mathrm{x}} \mathrm{g}_{\mathrm{y}}\right)$
represent the minimal effort with which every observed DMU realise the efficient technology corresponding of a fixed ( $\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}$ ) direction and $\left(g_{x}^{T_{\text {min }}} g_{\mathrm{y}}^{\mathrm{T}_{\text {min }}}\right.$ ) is the direction corresponding of $f_{\text {effopt }}^{T}$.
If $f_{\text {eff }}^{i}$ is the minimal effort of $\mathrm{DMU}_{\mathrm{i}}$ for become efficient and $f_{\text {effopt }}^{T} \neq 0$ then the ratio: $\mathrm{R}=\frac{\sum_{\mathrm{i}=1}^{\mathrm{k}} f_{\text {eff }}^{i}}{f_{\text {effopt }}^{T}}$ represent how many is smaller total effort of DMUs to become efficient if each to pertain of itself optimal direction to the variant when the direction is same for everything. Evidently $0 \leq \mathrm{R} \leq 1$. Because for each DMU corresponds a selfdirection is naturally to try to group the observed DMUs to their direction.
reveal how many times is more difficult to realise the efficient technology corresponding of $\left(\mathrm{g}_{\mathrm{x}}^{?}, \mathrm{~g}_{\mathrm{y}}^{?}\right)$ direction than easiest variant. Evidently $E f f_{A L}^{\theta} \geq 1$.
By and large, for a fixed direction ( $\mathrm{g}_{\mathrm{x}}, \mathrm{g}_{\mathrm{y}}$ ) the value:

A possible variant is to angle of them. If g $=\left(\mathrm{g}_{\mathrm{x}}^{i}, \mathrm{~g}_{\mathrm{y}}^{i}\right)$ is optimal direction of $\mathrm{DMU}_{\mathrm{i}}$ and $\mathrm{g}^{j}=\left(\mathrm{g}_{\mathrm{x}}^{j}, \mathrm{~g}_{\mathrm{y}}^{j}\right)$ for $\mathrm{DMU}_{\mathrm{j}}$ then:

$$
\frac{\left\langle g^{i} g^{j}\right\rangle}{\left\|g^{i} \cdot \mid g^{j}\right\|}=\cos \alpha
$$

where $\alpha_{\mathrm{ij}}$ is the measure of angle among the directions of two DMU and $\langle x, y\rangle,\|x\|$ and $\|y\|$ are usual notations for the scalar product and the norm of vectors.
Therefore: $\alpha_{\mathrm{ij}}=\arccos \frac{\left\langle\mathrm{g}^{\mathrm{i}} \mathrm{g}^{\mathrm{j}}\right\rangle}{\left.\left\|\mathrm{g}^{\mathrm{i}}\right\| \cdot \| g^{\mathrm{j}}\right\rangle}$.
and two DMUs are more approaching if $\alpha_{\mathrm{ij}}$ is smaller. Then: $F_{0}^{\alpha}=\left\{\mathrm{DMU}_{\mathrm{i}} / \alpha_{0 \mathrm{i}} \leq \alpha\right\}$ is the set of DMUs of whom optimal directions make an angle less or equal with $\alpha$. Also, it is possible to group the DMUs to them effort for become efficient.
However, the most difficult problem remains the estimate of function $\mathrm{f}_{\text {eff }}$.
A first observation is than, for the preceding compute, is sufficient to define the function $\mathrm{f}_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}, \mathrm{y}\right)$ only for ( $\mathrm{x}_{0}-\mathrm{x}, \mathrm{y}$ $\left.-y_{0}\right) \geq 0$ and, for compute the necessary effort for one fixed DMU ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ), is sufficient to define the function $\mathrm{f}_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}, \mathrm{y}\right)$ only for the variation of x and y . Also, for compute the minimal necessary effort is sufficient to know the values of $\mathrm{f}_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}, \mathrm{y}\right)$ only for ( $\mathrm{x}, \mathrm{y}$ ) belonging of convex hull of technology.

## 4. Examples

Simplest variant is to estimate for each input the necessary effort for reduction with one unit and for each outputs the necessary effort for increase with one unit, to considerate ca the effort is linear in each input and output and that the necessary effort for a combination of reduction and increasing is equal with the sum of the individual efforts.
If $\left(c_{x}, c_{y}\right)$ represent the vector of the unit effort then the function $f_{\text {eff }}$ is:

$$
f_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}, \mathrm{y}\right)=\left(\mathrm{c}_{\mathrm{x}}, \mathrm{c}_{\mathrm{y}}\right)^{\mathrm{T}}\left(\mathrm{x}_{0}-\mathrm{x}, \mathrm{y}-\mathrm{y}_{0}\right)
$$

where $\left(x_{0}-x, y-y_{0}\right) \geq 0$ and $\left(c_{x}, c_{y}\right) \geq 0$.
In this case the problem at step 5 . is:

$$
\begin{gathered}
f_{e f f}^{i}=\min _{\lambda}\left(\mathrm{c}_{\mathrm{x}} \mathrm{c}_{\mathrm{y}}\right)\left(x_{0}-X_{i}^{T} \lambda, Y_{i}^{T} \lambda-y_{0}\right) \\
\left\{\begin{array}{l}
\sum_{j=1}^{\operatorname{card}\left(F_{i}\right)} \lambda_{j}=1 \\
X_{i}^{T} \lambda \leq x_{0} \\
Y_{i}^{T} \lambda \geq y_{0} \\
\lambda \geq 0
\end{array}\right.
\end{gathered}
$$

and it is a linear program.
Moreover, if $\mathrm{u}=x_{0}-X_{i}^{T} \lambda$ and $\mathrm{v}=$ $Y_{i}^{T} \lambda-y_{0}$ the problem become:

$$
\begin{gathered}
f_{\text {eff }}^{i}=\min _{\lambda, u, v}\left(\mathrm{c}_{\mathrm{x}}^{\mathrm{T}} \mathrm{u}+\mathrm{c}_{\mathrm{y}}^{\mathrm{T}} \mathrm{v}\right) \\
\left\{\begin{array}{c}
\sum_{j=1}^{\operatorname{cardd}\left(F_{i}\right)} \lambda_{j}=1 \\
X_{i}^{T} \lambda+u=x_{0} \\
Y_{i}^{T} \lambda-v=y_{0} \\
\lambda, u, v \geq 0
\end{array}\right.
\end{gathered}
$$

Because the objective function has the every coefficients positive, the minimum is obtaining when it is a maximal number of $u$ and $v$ equals with 0 . Also, because in general the matrix of system have $m+n+$ 1 lines and $2 m+2 n$ colons this number is in general equal of $m+n-1$. We would a single $u$ or $v_{j}$ different of 0 so direction of projection is:
$\left(\mathrm{g}_{\mathrm{x}}^{0}, \mathrm{~g}_{\mathrm{y}}^{0}\right)=\left(\mathrm{x}_{0}-\mathrm{x}_{0}^{\mathrm{pp}}, \mathrm{y}_{0}^{\mathrm{pp}}-\mathrm{y}_{0}\right)=\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)-I_{m+n}^{p}\left(\mathrm{u}_{\mathrm{i}}, \mathrm{v}_{\mathrm{j}}\right)$ where $I_{m+n}^{p}$ is a $1 \times(\mathrm{m}+\mathrm{n})$ with every components equal of 0 except for the component corresponding of variable $u$ or $\mathrm{v}_{\mathrm{j}}$ different of 0 . Therefore, for a such
function of effort, the problem is reducing at the scaling down only one input or the scaling up only one outputs and fixed all other inputs and outputs.
The solution corresponding of direction for which the value of effort functions is minimal in projection point.
An other simple variant is to considerate than effort function depend only at the distance among ( $\mathrm{x}_{0}, \mathrm{y}_{0}$ ) and ( $\mathrm{x}, \mathrm{y}$ ):

$$
f_{e f f}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}, \mathrm{y}\right)=\mathrm{f}\left(\left\|(\mathrm{x}, \mathrm{y})-\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)\right\|\right)
$$

If this function is linear $f\left(\left\|(x, y)-\left(x_{0}, y_{0}\right)\right\|\right)$ $=\mathrm{c} \cdot\left\|(\mathrm{x}, \mathrm{y})-\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)\right\|, \mathrm{c} \in R_{+}$then the problem is reducing at compute geometric distance from $\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)$ at convex hull of technology. Also, she can be increasing or decreasing as the marginal effort is elder or less of 1 .
Combining the both variant, we obtain an effort function of type:
$f_{\text {eff }}\left(\mathrm{x}_{0}, \mathrm{y}_{0} ; \mathrm{x}, \mathrm{y}\right)=\mathrm{f}\left(\left\|\left(\mathrm{c}_{\mathrm{x}}, \mathrm{c}_{\mathrm{y}}\right)^{\mathrm{T}}\left(\mathrm{x}_{0}-\mathrm{x}, \mathrm{y}-\mathrm{y}_{0}\right)\right\|\right)$
However, the problem of estimate of function $£_{f f}$ is open and most probable it depends from peculiarity of each analysed situation.
